2 phyloMed

data.cecal

Real data

Description

This data is derived from a real microbiome dataset (Cho et al., 2012), which includes 48 samples (38 in antibiotics vs. 10 in controls).

Usage

```
data(data.cecal)
```

Format

data.cecal contains the following components:

treatment treatment indicator: Antibiotics group and control group are coded as 1 and 0, respectively.

mediators an abundance matrix with the top 100 most abundant taxa.

outcome body fat percentage.

tree a phylogenetic tree.

phyloMed

Phylogeny-based test of mediation effect in microbiome (PhyloMed)

Description

phyloMed enables us to test the mediation effect in high-dimensional microbial composition. The method leverages the hierarchical phylogeny relationship among different microbial taxa to decompose the complex mediation model on the full microbial composition into multiple simple independent local mediation models on subcompositions. The phyloMed function (a) performs the mediation test for the subcomposition at each internal node of the phylogenetic tree and pinpoint the mediating nodes with significant test p-values; and (b) combine all subcomposition p-values to assess the overall mediation effect of the entire microbial community.

phyloMed 3

Usage

```
phyloMed(
   treatment,
   mediators,
   outcome,
   tree,
   method = "JC",
   lambda = 0.5,
   confounders = NULL,
   interaction = FALSE,
   fdr.alpha = 0.05,
   n.perm = NULL,
   verbose = FALSE,
   graph = FALSE
)
```

Arguments

treatment A numeric vector of the treatment.

mediators A named numeric matrix containing microbiome abundance. Each row is a

subject and each column is a taxon. Row name contains the subject ID and

column name contains the taxon name.

outcome A numeric vector of continuous or binary outcomes.

tree A phylo-class object. The tip labels in the tree should overlap with the col-

umn names in the mediators matrix.

method An optional character string denotes the method to used in estimate proportion

of null. Can be abbreviated. Default method is "JC", an alternative method is

"Storey".

lambda An optional numeric tuning parameter between 0 and 1, need to be specified

when the method is "Storey". Default is 0.5.

confounders An optional numeric vector or matrix containing confounders that may affect

the treatment, mediators and outcome. Each row is a subject and each column

is a specific confounder, e.g., age or sex. Default is NULL.

interaction An optional logical value. If TRUE, the interaction term between treatment and

mediator will be taken into account. Default is FALSE.

fdr. alpha An optional numeric value for the desired FDR significance level in identifying

mediating nodes on the tree. Default is 0.05.

n.perm An optional numeric value for the maximum number of permutations. Default

is NULL. See Details.

verbose An optional logical value. If TRUE, information of the test on each node will be

printed. Default is FALSE.

graph An optional logical value. If TRUE, generate a graph that contains a phylogenetic

tree with identified mediating nodes highlighted. Default is FALSE. See Details.

4 phyloMed

Details

PhyloMed uses the treatment-mediator association test p-value and mediation-outcome association test p-value to construct the subcomposition mediation test statistic at each local model (Hong et al., Manuscript). The two p-values can come from either the asymptotic test or the permutation test. Asymptotic test is faster but less accurate when the study sample size is small. By default (n.perm=NULL), only asymptotic test will be performed. Otherwise, if n.perm is set to a positive number, results from two versions of PhyloMed will be output, one based on the asymptotic p-value and the other based on the permutation p-value. Graph only highlights the mediating nodes identified from permutation version when both versions are performed.

Value

A phyloseq-class object named clean. data and a list named rslt.

clean.data contains the following components:

sample_data Input treatment, outcome and confounders.

otu_table The abundance data for the taxa that are present on the tips of the phy_tree.

phy_tree The binary and rooted phylogenetic tree with tips exactly match the taxa in the

otu_table.

If n.perm is not NULL, the function will return two lists in rslt named PhyloMed. A and PhyloMed. P, respectively. Otherwise, only one list named PhyloMed. A will be returned.

Each list contains the following components:

node.pval A numeric vector of subcomposition mediation p-values for all internal nodes.

sig.clade A list of significant nodes with their descendants.

null.prop A vector of the estimated proportion of different types of null hypotheses across

all local mediation tests.

global.pval A global test p-value using Simes' method (Simes, 1986).

If graph is TRUE, the phylogenetic tree will be plot. The size of the circle at each internal node is proportional to $-\log_{10}(\text{subcomposition p-value})$, the larger circle indicates a smaller p-value. The significant nodes are highlighted by blue rectangle.

Examples

```
# Load real data
data(data.cecal)
# Run test
Trt = data.cecal$treatment
M = data.cecal$mediators
Y = data.cecal$outcome
tree = data.cecal$tree
rslt.phylomed = phyloMed(Trt, M, Y, tree, graph = TRUE)
```

prepareTree

Prepare phylogenetic tree to be used in phyloMed function

Description

The phyloMed function requires a rooted and binary tree as input. The prepareTree is an utility function that allows users to preprocess their tree if it is unrooted and/or non-binary. The tree output from prepareTree function can be directly fed into phyloMed function.

Usage

```
prepareTree(tree, verbose = FALSE)
```

Arguments

tree A phylo-class object.

verbose An optional logical value. If TRUE, tree manipulation process will be printed.

Default is FALSE.

Value

A binary and rooted tree with nodes and tips conform with following phylo standards:

- The internal nodes are numbered with value larger than the number of tips.
- The internal nodes are numbered sequentially, with values increasing away from the root.
